**Abstract:** The knowledge on spiders of the Czech Republic has substantially improved since the second version of the national Red List was published, mainly due to large-scale field records and the establishment of an extensive, searchable electronic database of both retrospective and prospective records. Meanwhile, Central European spiders have undergone substantial changes in abundance and distribution. In this report, an updated Red List is presented and compared with the previous editions from 1992 and 2002, assessing all 879 spider species known to occur in the Czech Republic. For the first time, the abundance, area of occupancy and population trends were calculated for each of the species using the data from the Czech Arachnological Society recording scheme. Twenty-seven species (3% of the total) were classified as Regionally Extinct (RE), 92 (10%) as Critically Endangered, 115 (13%) as Endangered, 155 (18%) as Vulnerable, and 121 (14%) were classified as Least Concern species. Some species listed in the previous version of the Red List were found to live also in non-endangered habitats or to be more common than previously thought, and were thus removed from the list or reclassified to the lower Red List categories. Additionally, several species with dramatically decreasing abundance were identified, among them *Ozyptila rauda*, *Agyneta equestris*, *Agyneta mollis*, *Kishidaia conspicua*, *Clubiona genevensis* and *Centromerus semiater*. The results confirm that spiders are a highly threatened group of arthropods in the Czech Republic, and the updated Red List provides an important foundation for defining conservation priorities.

**Key words:** evidence-based conservation; extinction risk; invertebrate surveys; monitoring; Red List; spiders; threatened species

## Introduction

The impact of human development on landscape and climate changes during the 20<sup>th</sup> and 21<sup>st</sup> centuries have caused rapid and substantial changes to the distribution and abundance of spiders both in Central Europe and elsewhere (Gobbi et al. 2006; Chen et al. 2011; Leroy et al. 2013, 2014; Heneberg & Řezáč 2014; Tropek et al. 2014; Košuliš et al. 2014). These changes have prompted the establishment of a database of records on spider occurrence and the need for a conservation response. In the Czech Republic, the electronic faunistic database was established at <http://cas.zlej.net> (cited as 15 Oct. 2014) by the Czech Arachnological Society (CAS), and it contains both prospectively added records as well as retrospective data retrieved from previously published literature, including gray literature such as various unpublished records. While the exact location of sampling sites and sampling dates are password-protected, the number of findings per grid of the Czech faunistic grid mapping is publicly available, as well as the decades in which the records were

obtained. Establishment of such extensive and non-selective evidence allowed us to address the actualization of the Red List of Czech spiders.

The Red Lists of spiders are available for a number of European countries, including most countries in Central Europe. Among them are the regularly updated Red List of German spiders (Blick et al. in press.), the recently formed Red List of Carpathian spiders (Gajdoš et al. 2014), and Red Lists of Poland (Starega et al. 2002), Slovakia (Gajdoš & Svatoň 2001), the Austrian state of Carinthia (Komposch & Steinberger 1999), Belgian Flanders (Maelfait et al. 1998), Norway (Åkra et al. 2006), Finland (Rassi et al. 1992), Sweden (Ehnström et al. 1993), Great Britain (Merrett 1991) and Italy (Gropali & Priano 1993). In the Czech Republic, the first version of the Red List of Czech spiders, published by Buchar (1992), was allowed to contain only 30 spider species, all required to represent large and spectacular spider species occupying locally highly endangered habitats. This approach rather resembled the enactment of the nature protection law, where prominent flagship species are generally priori-

tized over small ones and those with nontrivial species determination (cf. current species-specific nature protection laws in nearly any country worldwide). Later, Buchar & Růžička (2002) compiled a catalogue of Czech spiders, and utilized its content in the construction of the updated Red List of Czech spiders (Růžička 2005). In this list, the IUCN criteria were applied for the first time when selecting the species to be red-listed. However, Růžička had to use relatively limited knowledge on the distribution of most spider species; thus, the selection of species was still strongly biased. In this second Red List, only one species, *Lycosa singoriensis*, was suggested to be regionally extinct (RE), whereas seven other species were known to be absent since 1950 but were not listed as regionally extinct because of doubts on whether the last individual of such species (usually inconspicuous or resident in subterranean habitats) had already died. *Lycosa singoriensis* is once again recognized as a member of Czech spider fauna because it re-colonized the southeastern parts of the Czech Republic in the early 2000s. Buchar & Růžička (2002) and Růžička (2005) classified another 53 species as critically endangered (CR), 85 species as endangered (EN), 71 species as vulnerable (VU), and 49 species as low risk / near threatened (listed as the LC species in this manuscript).

Although the first data on the distribution of spiders in the Czech Republic date back to the late 19<sup>th</sup> century, the data have started to strongly accumulate since the 1990s with the onset of pitfall-trapping and later with the government-stimulated onset of extensive monitoring of the biodiversity present within the Czech nature reserves. Over half of the Czech spider records available represent the years 1990–2014. Thus, when performing field work and when assessing the time- and site-matched datasets contained in the CAS database, we noticed that a significant part of the 2005 Red List is outdated, and does not reflect actual trends in the distribution and abundance of particular species.

In this report, we use the evidence-based approach aimed to improve the 2005 Red List to reflect the extensive evidence on the distribution, abundance and population trends of Czech spiders gained during the last two decades.

## Material and methods

We follow the nomenclature according to the World Spider Catalog (2015). The exceptions are *Dysdera lantosquensis* (valid species, Řezáč et al. 2008), *Eresus illustris* (valid species, Kůrka et al. 2015), *Enoplognatha bryjai* (new species, Řezáč & Heneberg in press.) and *Heliophanus pouzdranensis* (valid species, Kůrka et al. 2015).

### Data sources

We used data on all Czech spider species (not only the endangered ones) from the electronic database of the Czech Arachnological Society. For species identified in the Czech Republic only recently, the number of published records was retrieved from current literature as summarized in the recently published compendium by Kůrka et al. (2015). In summary, 134,005 records of 879 species were analyzed, of

which 70,330 records of 820 species were registered in 1990–2014.

### Criteria

The modified IUCN criteria were followed at the regional level as suggested by Gärdenfors et al. (2001) as long as the data available permitted.

For the presentation of distribution of species, a Central European grid map was used. A 10' × 6' grid produces grid fields of about 12 × 11 km. We evaluated the number of grid squares, in which the species had been recorded.

We evaluated also the habitat status, categorized as rare, disappearing, already rare and disappearing, or widespread (Kučera 2005).

Further, we considered sensitivity to habitat degradation, such as eutrophication, changing habitat management, steppes overgrown with shrubs and trees, Aeolian sands overgrown with trees, particularly pine forest plantations, or trampling (Thomas et al. 2001; Warren et al. 2001; Buchholz 2010; Řezáč & Heneberg 2014).

Population decline was expressed as a ratio of CAS database records from 1990–2014 compared to the total number of records since the 19<sup>th</sup> century. The number of records obtained in 1990–2014 composes 52% of the total number of records in the CAS database. Minor fluctuations in the number of records may reflect the shift in interest of local arachnologists for different habitats or different families. Nevertheless, anything above or below the arbitrarily chosen 20–80% threshold was considered as a significant shift reflecting the IUCN A2 criterion (IUCN 2012). Most spiders are not as prominent and frequently collected as, e.g., butterflies (Fox et al. 2011), and they follow multiple and often semifossorial life strategies. Thus, the population changes observed based on the CAS database records were considered only as the auxiliary criterion, which was corroborated by the personal experience of the authors of this study and our acknowledged colleagues. Sampling sites were visited repeatedly throughout long periods of time to avoid any bias caused by the uneven sampling intensity of species contained in the CAS database.

The presence of suitable habitats occupied by identical species in the surrounding Central European countries, i.e., Germany (Blick et al. in press.), Austria (Komposch & Steinberger 1999), Slovakia (Gajdoš & Svatoň 2001) and Poland (Starega et al. 2002) were also considered. This criterion involved an assessment of whether the regional extinction threat determined based on the presence/absence data was affected by the existence of populations outside of the region in question by providing potential for a rescue effect (Gärdenfors et al. 2001; Keller et al. 2005). In particular, the species bound to alpine regions are extremely rare in the Czech Republic, but that is due to the very limited extent of such habitats within the country. In contrast, many of the rare steppe and Aeolian sands specialists are also rare at similar sites in the nearby countries, although such habitats are also considered as very limited in the Czech Republic.

We evaluated also the typical species-specific habitat preferences and the occurrence of species in three phytogeographic districts of the Czech Republic, namely Thermophilicum, Mesophyticum, and Oreophyticum (Buchar & Růžička 2002).

### Red list categories

**RE – Regionally Extinct.** These species were defined solely by the threshold criterion of the absence of species-specific records in the Czech Republic during the last 30 years (i.e., from 1984 onward).

Table 1. Summarized data on the new Red List of Czech spiders, indicating the total number of species in each suggested category and the classification of the species according to status of their habitat. The abbreviations of Red List categories are explained in Material and Methods.

Red list category	Number of species	Habitat status			
		Total	Rare	Disappearing	Already rare and disappearing
RE	26	19			7
CR	92	36	1		53
EN	115	45	13		59
VU	155	40	60		55
LC	121	40	61	18	2
ES	370	7	6	4	353
Total	879	187	141	196	355
Chao-1 estimate ± SD	923.6 ± 12.6				

**CR – Critically Endangered.** Species with less than 100 individuals recorded in the CAS database from the 19<sup>th</sup> century onward, and which originated from sampling sites at less than 10 grid squares, were recognized as potentially CR species. These species represent those bound strictly to the habitats limited in size and endangered by changes in the cultural landscape, at risk of regional extinction in the absence of proper management measures.

**EN – Endangered.** Species with less than 100 individuals recorded in the CAS database from the 19<sup>th</sup> century onward, and which originated from sampling sites at 50 or less grid squares, were recognized as potentially EN species.

**VU – Vulnerable.** Species with less than 500 individuals were recorded in the CAS database from the 19<sup>th</sup> century onward, and which originated from sampling sites at 50 or less grid squares, were recognized as potentially VU species.

The EN and VU species represent infrequently found taxa bound strictly to habitats limited in size, and endangered by changes of the cultural landscape though not at risk of immediate extinction. Species classified in these two categories differ in the number of habitat types they are able to colonize, in the extent of the habitats occupied, in the endangerment of their habitats, in their sensitivity to habitat degradation, and in their overall abundance in the Czech Republic and abroad. Nowadays we have extensive knowledge even about species of cryptic habitats such as subterranean spaces (for example, Růžička et al. 2013) or tree canopies (for example, Kubcová & Schlaghamerský 2002). Thus, probability of exaggeration of endangerment in such species caused by lack of knowledge decreased.

**LC – Least Concern.** These species represent relatively common species that are bound to narrowly defined habitats and threatened by ongoing changes of the cultural landscape.

**ES – Ecologically Sustainable.** These species represent ubiquitous species, synanthropic species, species utilizing habitats present in stable or increasing extent and quality, and those commonly colonizing newly emerging habitats.

To predict the total number of spider species of the Czech Republic, we calculated the Chao-1 estimator using the program available at <http://www2.biology.ualberta.ca/jbrzusto/rarefact.php> (accessed 15 Oct 2014).

## Results

The complete list of taxa included in the Red List is given in Appendix 1, and the numbers in the particular

Red List categories are shown in Table 1. Of the total 879 taxa of the Czech arachnofauna evaluated (representing the whole Czech arachnofauna known at the time of manuscript submission), 509 (57.9%) were categorized as RE, CR, EN, VU or LC. Of the Red-Listed taxa, 26 (5.1% of the total number listed) were recognized as Regionally Extinct, 92 (18.1%) were Critically Endangered, 115 (22.6%) were Endangered, 155 (30.5%) were Vulnerable, and 121 (23.8%) were Least Concern species.

Although the stability of the categories used in the present and past versions of the Red List suggests the possibility of identifying trends in the occurrence of threatened and endangered taxa in the Czech Republic over time, in most cases, the changes in suggested species categorization reflect the improvement in our knowledge on these species and their habitat requirements. However, there are some exceptions represented, e.g., by the reclassification of species with increasing abundance such as *Lycosa singoriensis* (CR→LC, recolonization of the Czech Republic in the 21<sup>st</sup> century), *Uloborus walckenaerius* (CR→EN, 95% of records from 1990–2014), *Talavera milleri* (CR→EN, 43% of records from 1990–2014), *Porrhomma errans* (CR→ES, 78% of records from 1990–2014), *Dysdera hungarica* (CR→ES, 100% of records from 1990–2014), *Zodarion italicum* (EN→ES, 100% of records from 1990–2014), *Cheiracanthium punctorum* (EN→ES, 87% of records from 1990–2014), *Tetragnatha shoshone* (VU→ES, 100% of records from 1990–2014 – although its habitats are restricted only to those of conservation interest, the species is considered as alien), *Megalepthyphantes pseudocollinus* (EN→LC, 100% of records from 1990–2014), *Entelecara flavipes* (VU→LC, 70% of records from 1990–2014), *Titanoeca schineri* (VU→LC, 71% of records from 1990–2014) and *Theonina kratochvili* (EN→VU, 76% of records from 1990–2014). Similarly, species with dramatically decreasing abundance were reclassified; among them were *Ozyptila rauda* (VU→CR, 0% of records from 1990–2014), *Agyneta equestris* (NT→EN, 9% of records from 1990–2014), *Kishidaia conspicua* (VU→EN, 0% of records from 1990–2014), *Clubiona genevensis* (EN→CR, 13% of records from 1990–2014), *Centromerus semiater* (ES→EN, 7% of records from

Table 2. Indicators of area of occupancy, population status and population decline values of species classified according to the new Red List of Czech spiders. This includes the total number of records of each species, number of squares of the Czech faunistic grid mapping occupied, proportion of records from the years 1990–2014 relative to the total number of species-specific records [%], and the Red List status of each species. To allow tabulation of the data including all 879 Czech spider species, the three indicators are shown as categorized values.

Total number of records	Number of grids occupied	Relative share of records from 1990–2014 (%)	Red list status					
			RE	CR	EN	VU	LC	ES

Explanations: \*Synanthropic species. \*\* Species of subterranean habitats. †Of that one synanthropic and one alien species. ‡Of that 14 synanthropic and/or alien species. The abbreviations of Red List categories are explained in Material and Methods.

1990–2014) and *Porrhomma convexum* (ES→LC, 11% of records from 1990–2014).

One of the main criteria considered for the listing of a particular species was the habitat status. With two exceptions, all 509 listed species are limited to rare and/or disappearing habitats, which are frequently narrowly characterized by precise requirements for management, vegetation cover and bedrock type. All the RE species were limited to rare or already rare and disappearing habitats. Some listed species utilized habitats, which are still relatively common but disappearing. Such habitats hosted 1% of the CR species, 11% of the EN species, 39% of the VU species and 50% of the

LC species (Table 1). The ES species limited to the rare and/or disappearing habitats represented prevalently alien species, such as *Tetragnatha shoshone*, and species with strong and/or increasing populations across Central Europe, such as *Xysticus acerbus*, *Hilaira excisa*, *Walckenaeria acuminata*, *Theridion hemerobium*, *Pardosa hortensis* and *Porrhomma microps* (Appendix 1, Table 2)<sup>1</sup>.

When considering habitat types, the highest share of listed species resided in open habitats (76% of the total open habitat specialists, of which 3.2% were represented by RE species) and wetlands (75% listed, 4.8% RE species). Of the forest specialists, 46% were listed (1.6% RE species). Of the subterranean species, 45% were listed (6.9% RE species, but caution is needed in the case of relatively infrequently collected species of subterranean habitats). None of the synanthropic species were listed, and only 1% of the ubiquitous species and species utilizing multiple habitats were listed (Table 3). The Czech Republic also hosts nine

<sup>1</sup> W. Nentwig (in litt.) noticed that also *Urozelotes rusticus* and *Zelotes puritanus* might be considered as species introduced to Europe by humans. However, the conclusive evidence is absent so far, *Urozelotes rusticus* has not been found in the Czech Republic for 80 years and *Zelotes puritanus* occurs in the Czech Republic exclusively at sites of high conservation interest.

Table 3. Distribution of the Czech spider species across major habitat types.

Red list status	Habitat type						
	Open	Wetlands	Forests	Alpine	Subterranean	Synanthropic	Ubiquitous/multiple
Number of species							
RE	11	9	3	1	2		
CR	57	21	10	2			
EN	62	38	14	2	1		
VU	77	41	29	3	5		
LC	53	32	30		5		1
ES	83	46	99	1	16	34	91
Total	343	187	185	9	29	34	92

The abbreviations of Red List categories are explained in Material and Methods. Open – any terrestrial habitats without trees and shrubs or with only solitary trees and shrubs in lowlands and uplands. Wetlands – any wetlands, including fishponds, littoral zones of lakes, fens and peat bogs. Forests – habitats with dominant tree or bush stratum. Alpine – open habitats in the alpine zone. Subterranean – subterranean habitats like caves or scree slopes. Synanthropic – species living in synanthropic habitats (not necessarily exclusively). Ubiquitous / multiple – species living in two or more of the previously listed habitat types.

Table 4. Occurrence of the spider species in the Czech climatic-phytogeographic districts. The abbreviations of Red List categories are explained in Material and Methods.

Red list status	Climatic phytogeographic district						
	Oreo-phyticum	Oreo- and Mesophyticum	Meso-phyticum	Meso- and Thermophyticum	Thermophyticum	All three zones	Regularly or occasionally at/in the buildings
Number of species							
RE	6		6		14		
CR	6	1	18	8	58		
EN	19	8	19	19	49	2	
VU	12	13	41	43	43	2	1
LC	8	11	43	39	16	2	2
ES	10	61	54	140	10	50	45
Total	61	94	181	249	190	56	48

alpine spider species, eight of which are listed and one of which is Regionally Extinct. However, alpine habitats are highly limited across the country, and thus further faunistic research is needed to confirm that all eight alpine species deserve their current status.

When we analyzed the listed spider species according to their occurrence in phytogeographic districts of the Czech Republic (which was not among the criteria used for the Red List formation), we noticed that 100% of the RE species had its previous distribution range restricted to only a single phytogeographic region, which is also true for 90% of the CR species, 75% of the EN species, 62% of the VU species, 55% of the LC species but only 20% of the ES species (Table 4).

Despite being rare in the Czech Republic, several species were not listed or were listed in a category lower than that which would correspond to their abundance, population trend and area of distribution because they were common and/or increasing in the surrounding countries. These species included, for example, *Uloborus walckenaerius*, *Xysticus acerbus*, *Mysmenella jobi*, *Megalepthyphantes pseudocolinus* and *Arctosa maculata*. Although the Red List provided reflects the species abundance in the surrounding

countries, overlap with the Red Lists of Germany, the Carpathians (including Slovakia) and Poland is highly limited (Fig. 1). Interestingly, there is only a single species listed as RE, CR or EN in all four Red Lists compared (*Mecynargus morulus*). The newly proposed Red List of Czech spiders contains 76% of the species listed in the Carpathians, 67% of the species listed in Germany, and 54% of the species listed in Poland (Fig. 1).

## Discussion

The new Red List assessment was based on the most comprehensive monitoring data available for Czech spiders. The results are consistent with the previous assessment based on the personal experience of the author of the previous Red List and confirm that spiders are a highly threatened group in Central Europe, particularly in the Czech Republic (Růžička 2005). This study found 44% of spider species to be either RE or threatened (CR, EN or VU). This compares with 62% of bees (Straka 2005), 47% of Czech native lampreys and fish (Lusk et al. 2004), 46% of Czech native vascular plant species (Grulich

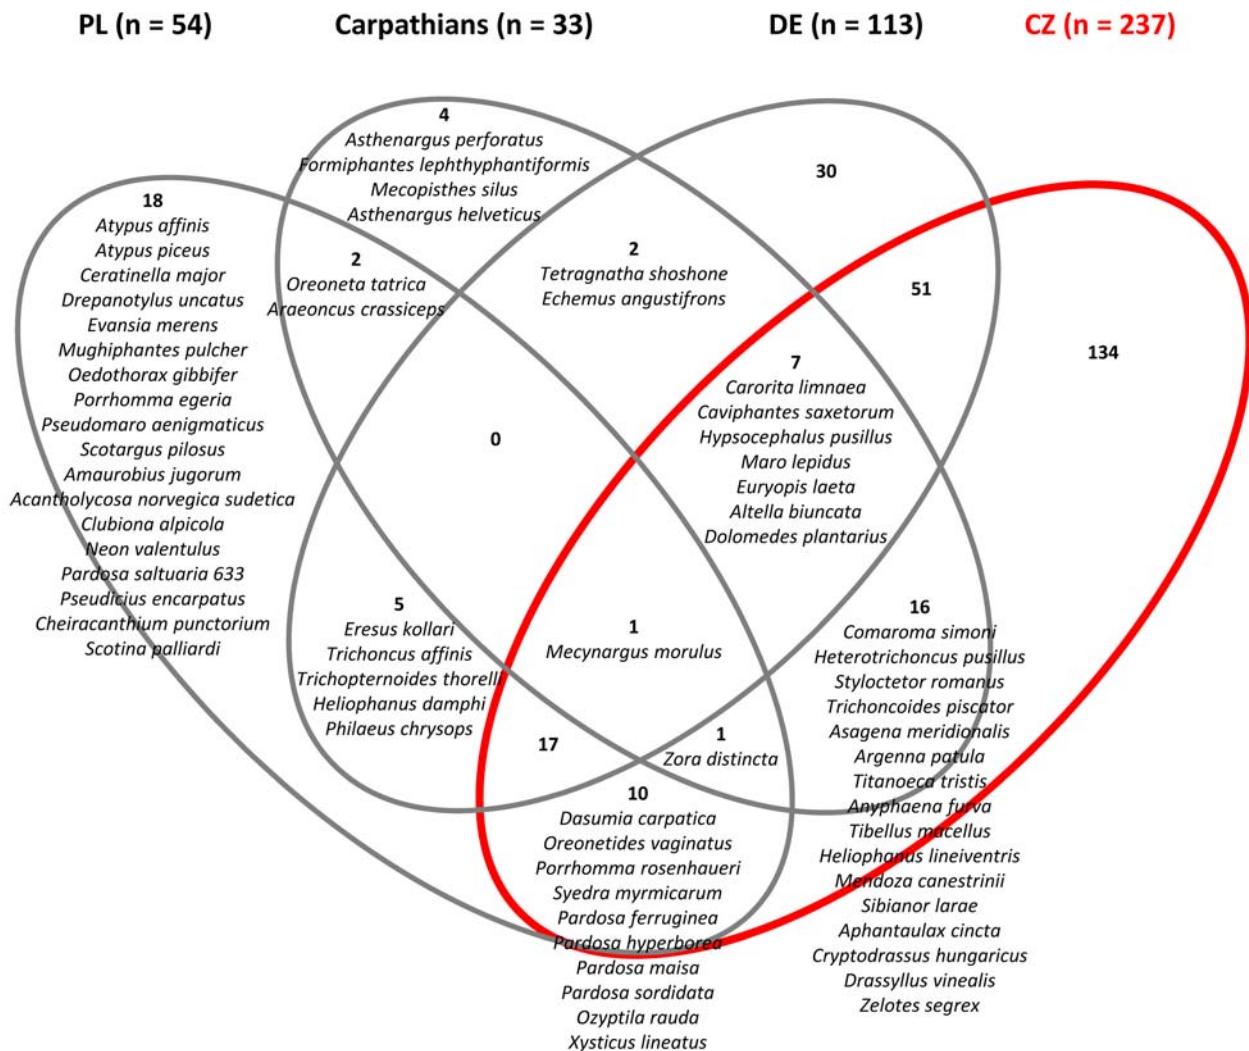

Fig. 1. Venn diagram showing the overlap between rare species classified as Regionally Extinct (RE), Critically Endangered (CR) and Endangered (EN) in the new Red List of Czech spiders (CZ; this study), new Red List of Germany (DE; Blick et al. in press.), Red List of Spiders of the Carpathian Mountains (Carpathians; Gajdoš et al. 2014), and Red List of Poland (PL; Starega et al. 2002). The number of species listed as RE, CR or EN in one or more countries is indicated; for the small groups of species, the species names are disclosed as well.

2012) and 33% of Czech bryophytes (Kučera et al. 2012).

A comparison with previous Red List assessments of spiders shows that the number of species considered to be threatened (RE, CR, EN or VU) has grown rapidly from 30 taxa (3.6% of Czech spider species; Buchar 1992) and 210 species (25%; Růžička 2005) to 388 species (44%; this study). Three main factors, acting frequently in combination but exerting different effects on different species, may be responsible for this trend: continued decline, improved data and improved inclusion criteria.

From the evaluation, it is clear that the abundance, local distribution range area and population trends cannot be used as the sole rationale for selecting red-listed species in a diverse group of species such as the spiders, particularly for species with a limited likelihood to be captured by the most widespread capture techniques. Nevertheless, the databank of species records is very helpful in setting threshold values to evaluate

the status of a particular species (Table 2). Repeated monitoring at a set of well-defined transects would be very helpful to corroborate the hitherto available data on spider population trends. Similar pan-European programs exist already for birds (Reif et al. 2008; Musilová et al. 2014) and attempts have also been conducted for selected other taxa. Only such long-term systematic monitoring at a representative selection of sites visited repeatedly at regular time intervals (e.g., five years) can provide a definitive answer on population trends of most of the spider species, particularly those considered thus far as common or Least Concern species. In addition to the monitoring of natural habitats, usually in nature reserves, attention should shift also to newly emerging habitats formed as a by-product of human activities. Post-industrial areas, particularly those affected by mining, quarrying and military training possess a yet overlooked potential to serve as replacement habitats for very diverse biota, including spiders (Tropék et al. 2010, 2014; Heneberg & Řezáč 2014). This po-

tential is still poorly reflected in the country-specific regulatory laws (Damigos 2006; Heneberg 2013). The construction of Red Lists should also reflect the context of particular sites of occurrence of the rare species as defined by Scolozzi et al. (2014). Connectivity and land-use changes may have a strong influence on the species-specific presence/absence data in sparsely occurring habitats, particularly in relation to the urbanization or agriculture intensification pressures within the increasingly human-dominated landscape.

In many instances, Red Lists act as drivers for biodiversity conservation both at the policy level and in terms of practical management of threatened species (Fox et al. 2011). They allow for the identification of a network of priority sites for conservation and stimulate further analyses of the taxa identified as threatened (Evans et al. 2009; Leroy et al. 2014; Řezáč & Heneberg 2014). This new Red List assessment thus provides an important foundation for improved monitoring outcomes of nature protection areas within the country and sets the threshold for further evaluations of spider population trends in Central Europe.

### Acknowledgements

The study was supported by the Ministry of Agriculture of the Czech Republic project MZe RO0415. V. Růžička was supported by the Academy of Sciences of the Czech Republic, v.v.i., project RVO: 60077344. We thank Theo Blick, Peter Gajdoš and Konrad Wisniewski for very helpful comments on the preliminary version of the Red List and for sharing their unpublished data. We thank Vítězslav Bryja, Jan Buchar, Petr Dolejš, Jan Erhart, Ivana Hradská, Vladimír Hula, Aleš Jelínek, Wolfgang Nentwig, Robert Tropek and members of the Czech Arachnological Society for suggestions on improvements of the 2005 Red List.

Received December 17, 2015

Accepted April, 2015

Appendix 1. Red List of Czech spiders, 3<sup>rd</sup> edition, and a complete checklist of Czech spiders. Acronyms of Red List categories are explained in Material and Methods. Total number of records shows the total number of species-specific records in the CAS database. Share of records from 1990–2014 (%) – share of records obtained in the years 1990–2014 relative to the total number of records. Number of grids occupied – the number of grid squares, in which the species has been recorded. Distribution – phytogeographic districts occupied: O = Oreophyticum, M = Mesophyticum, T = Thermophyticum. B – the occurrence at/in human buildings, I = Considered as alien species in the Czech Republic. RL – status according to the Red List of Spiders of the Carpathian Mountains (Carpathians; Gajdoš et al. 2014), new Red List of Germany (DE; Blick et al. in press.), and Red List of Poland (PL; Staręga et al. 2002). Abs = Species absent in the respective country; DD = Data deficient; I = Considered as a neobiont in Germany; NE = Threatened, but without fixation of the status in Germany. The order of families reflects the phylogenetic relationships (cf., for example, Kürka et al. 2015).

Family, species	Red list classification	Total number of records	Share of records from 1990–2014 [%]	Number of grids occupied	Distribution			RL of Carpathians	RL of Germany	RL of Poland
